K3 Surfaces and Lattice Theory

Ichiro Shimada

Hiroshima University

2014 Aug Singapore

Example

Consider two surfaces S_+ and S_- in \mathbb{C}^3 defined by

$$w^{2}(G(x,y) \pm \sqrt{5} \cdot H(x,y)) = 1$$
, where
$$G(x,y) := -9x^{4} - 14x^{3}y + 58x^{3} - 48x^{2}y^{2} - 64x^{2}y + 10x^{2} + 108xy^{3} - 20xy^{2} - 44y^{5} + 10y^{4},$$
 $H(x,y) := 5x^{4} + 10x^{3}y - 30x^{3} + 30x^{2}y^{2} + 10x^{3}y + 10x^{2}y^{2} + 10x^{3}y + 10x^{2}y^{2} + 10x$

Since S_+ and S_- are conjugate by $\operatorname{Gal}(\mathbb{Q}(\sqrt{5})/\mathbb{Q})$, they can *not* be distinguished algebraically. But S_+ and S_- are not homeomorphic (in the classical topology).

 $+20 x^2 y - 40 x y^3 + 20 y^5$.

Many examples of non-homeomorphic conjugate complex varieties are known since Serre (1964).

Introduction

Definition

A smooth projective surface X is called a K3 surface if

- \blacksquare \exists a nowhere vanishing holomorphic 2-form ω_X on X, and
- $\pi_1(X) = \{1\}.$

We consider the following geometric problems on K3 surfaces:

- enumerate elliptic fibrations on a given K3 surface,
- enumerate elliptic K3 surfaces up to some equivalence relation,
- enumerate projective models of a given K3 surface,
- enumerate projective models of K3 surfaces,
- determine the automorphism group of a given K3 surface,
-

Thanks to the theory of period mapping, some of these problems are reduced to computational problems in lattice theory, and the latter can often be solved by means of *computer*.

In this talk, we explain how to use lattice theory and computer in the study of K3 surfaces.

We then demonstrate this method on the problems of constructing Zariski pairs of plane curves of degree 6.

A *lattice* is a free \mathbb{Z} -module L of finite rank with a non-degenerate symmetric bilinear form

$$\langle \rangle : L \times L \to \mathbb{Z}.$$

Let L be a lattice of rank n. We choose a basis e_1, \ldots, e_n of L. The lattice L is given by the Gram matrix

$$G:=(\langle e_i,e_j\rangle)_{i,j=1,\ldots,n}$$
.

- ullet O(L) is the group of all isometries of L.
- *L* is *unimodular* if det $G = \pm 1$.
- The *signature* sgn(L) is the signature $L \otimes \mathbb{R}$.
- A lattice *L* is said to be *hyperbolic* if sgn(L) = (1, n 1), and is *positive-definite* if sgn(L) = (n, 0).
- A lattice *L* is even if $v^2 \in 2\mathbb{Z}$ for all $v \in L$.
- A sublattice L' of L is *primitive* if L/L' is torsion free.

Lattices associated to a K3 surface

hence is isomorphic to

K3 surfaces are diffeomorphic to each other. Suppose that X is a K3 surface. Then $H^2(X,\mathbb{Z})$ with the cup product is an even unimodular lattice of signature (3,19), and

$$U^{\oplus 3} \oplus E_8^{-\oplus 2}$$
,

where U is the hyperbolic plane with a Gram matrix

$$\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$$
,

and E_8^- is the negative definite root lattice of type E_8 .

The Gram matrix of E_8^-

The Néron-Severi lattice

$$S_X:=H^2(X,\mathbb{Z})\cap H^{1,1}(X)$$

of cohomology classes of divisors on X is an even hyperbolic lattice of rank \leq 20. Moreover the sublattice S_X of $H^2(X,\mathbb{Z})$ is primitive.

Problem

Suppose that an even hyperbolic lattice of rank \leq 20 is given. Is there a K3 surface X such that $S \cong S_X$?

We have the following corollary of the surjectivity of the period map:

Theorem

Let S be a primitive hyperbolic sublattice of $U^{\oplus 3} \oplus E_8^{-\oplus 2}$. Then \exists a K3 surface X such that $S \cong S_X$.

Problem

Suppose that an even lattice L and an even unimodular lattice M are given. Can L be embedded into M primitively?

A lattice L is canonically embedded into its dual lattice

$$L^{\vee} := \operatorname{Hom}(L, \mathbb{Z})$$

as a submodule of finite index. The finite abelian group

$$D_L := L^{\vee}/L$$

is called the discriminant group of L.

The symm. bil. form on L extends to a \mathbb{Q} -valued symm. bil. form on L^{\vee} , and it defines a finite quadratic form

$$q_L \colon D_L \to \mathbb{Q}/2\mathbb{Z}, \ \ \bar{x} \mapsto x^2 \bmod 2\mathbb{Z}.$$

Let M be an even unimodular lattice containing L primitively with the orthogonal complement L^{\perp} . Then we have

$$(D_L,q_L)\cong (D_{L^{\perp}},-q_{L^{\perp}}).$$

Conversely, if R is an even lattice such that

$$(D_L,q_L)\cong (D_R,-q_R),$$

then there exist an even unimodular lattice M and a primitive embedding $L \hookrightarrow M$ such that $L^{\perp} \cong R$.

Problem

Suppose that $s_+, s_- \in \mathbb{Z}_{\geq 0}$ and a finite quadratic form (D, q) are given. Can we determine whether \exists an even lattice L such that $\operatorname{sgn}(L) = (s_+, s_-)$ and $(D_L, q_L) \cong (D, q)$?

$\mathsf{Theorem}$

YES.

Corollary

We can determine whether a given even hyperbolic lattice of rank ≤ 20 is a Néron–Severi lattice of a K3 surface X or not.

ntroduction Lattice theory Polarizations Zariski pairs

Polarized K3 surfaces

For $v \in S_X$, let $\mathcal{L}_v \to X$ be the corresponding line bundle.

Definition

For $d \in \mathbb{Z}_{>0}$, a vector $h \in S_X$ of $h^2 = d$ is a polarization of degree d if $|\mathcal{L}_h| \neq \emptyset$ and has no fixed-components.

Let h be a polarization of degree d. Then $|\mathcal{L}_h|$ defines $\Phi_h: X \to \mathbb{P}^{1+d/2}$. We denote by

$$X \stackrel{\phi_h}{\longrightarrow} Y_h \stackrel{\psi_h}{\longrightarrow} \mathbb{P}^{1+d/2}$$

the Stein factorization of Φ_h . The normal surface Y_h is the projective model of (X, h), and has only rational double points as its singularities.

Example

A plane curve B is a *simple sextic* if B is of degree 6 and has only simple singularities (ADE-singularities; ordinary nodes, ordinary cusps, tacnodes, ...).

Let B be a simple sextic, and $Y_B \to \mathbb{P}^2$ the double covering branched along B. The minimal resolution X_B of Y_B is a K3 surface.

We denote by

$$\Phi_B: X_B \to Y_B \to \mathbb{P}^2$$

the composite of the min. resol. and the double covering, and by $h_B \in S_{X_B}$ the class of the pull-back of a line. Then h_B is a polarization of degree 2, and Y_B is its projective model.

Problem

Suppose that $h \in S_X$ with $h^2 > 0$ is given. Is h a polarization? If so, what is the ADE-type of $\operatorname{Sing}(Y_h)$?

We consider the second question first.

Proposition

The ADE-type of Sing Y_h is equal to the ADE-type of the root system $\{r \in S_X \mid \langle h, r \rangle = 0, \langle r, r \rangle = -2\}$.

The sublattice $\{x \in S_X \mid \langle h, x \rangle = 0\}$ is negative-definite.

Problem

Given a positive-definite lattice L and an integer d. Calculate the set $\{r \in L \mid \langle r, r \rangle = d\}$.

Suppose that we are given a triple $[Q, \lambda, c]$, where

- **Q** is a positive-definite $n \times n$ symmetric matrix with entries in \mathbb{Q} ,
- lacksquare λ is a column vector of length n with entries in \mathbb{Q} ,
- $c \in \mathbb{Q}$.

For $QT := [Q, \lambda, c]$, we define $F_{QT} : \mathbb{R}^n \to \mathbb{R}$ by

$$F_{QT}(v) := v Q^t v + 2 v \lambda + c.$$

We have an algorithm to calculate the finite set

$$E(QT) := \{ v \in \mathbb{Z}^n \mid F_{QT}(v) \leq 0 \}$$

by induction on n, and hence we can determine the ADE-type of $\operatorname{Sing} Y_h$.

Criterion for a polarization

Let L be an even hyperbolic lattice. Let \mathcal{P}_L be one of the two connected components of $\{x \in L \otimes \mathbb{R} \mid x^2 > 0\}$. We put

$$\mathcal{R}_L := \{ r \in L \mid r^2 = -2 \}.$$

Each $r \in \mathcal{R}_L$ defines a reflection s_r into the hyperplane $(r)^{\perp} := \{x \in \mathcal{P}_L \mid \langle x, r \rangle = 0\}$:

$$s_r: x \mapsto x + \langle x, r \rangle r$$

The closure in \mathcal{P}_L of each connected component of

$$\mathcal{P}_L \setminus \bigcup_{r \in \mathcal{R}_L} (r)^{\perp}$$

is a standard fundamental domain of the action on \mathcal{P}_L of

$$W(L) := \langle s_r \mid r \in \mathcal{R}_L \rangle.$$

Let $\mathcal{P}(X) \subset S_X \otimes \mathbb{R}$ be the positive cone that contains an ample class (e.g., the class of a hyperplane section). We put

$$N(X) := \{x \in \mathcal{P}(X) \mid \langle x, [C] \rangle \ge 0 \text{ for any curve } C \text{ on } X \}.$$

Proposition

This N(X) is a standard fundamental domain of the action of $W(S_X)$ on $\mathcal{P}(X)$.

It is obvious that, if h is a polarization, then $h \in N(X)$.

Proposition

Let $h \in S_X$ be a vector with $h^2 = 2$. Then h is a polarization if and only if $h \in N(X)$ and $\not\exists e \in S_X$ with $e^2 = 0$ and $\langle e, h \rangle = 1$.

Problem

Suppose that $h \in S_X$ with $h^2 > 0$ is given. Does h belong to N(X)?

Since N(X) is bounded by $(r)^{\perp}$, this problem is reduced to the following:

Problem

Suppose that we are given vectors $h, h_0 \in \mathcal{P}_L$. Then, for a negative integer d, calculate the set

$$\{ r \in S_X \mid \langle r, h \rangle > 0, \langle r, h_0 \rangle < 0, \langle r, r \rangle = -2 \}.$$

There is an algorithm for this task, and hence we can determine whether a given $h \in S_X$ with $h^2 = 2$ is a polarization or not.

Zariski pairs

For a simple sextic B,

- R_B : the ADE-type of $\operatorname{Sing} B$ (or of $\operatorname{Sing} Y_B$),
- $lue{}$ degs B the list of degrees of irreducible components of B.

We say that B and B' are of the same config type and write $B \sim_{\mathrm{cfg}} B'$ if

- $Arr R_B = R_{B'}, \operatorname{degs} B = \operatorname{degs} B',$
- their intersection patterns of irred. comps are same.

Example

Zariski showed the existence of a pair [B, B'] such that

- $Arr R_B = R_{B'} = 6A_2$, degs B = degs B' = [6], and
- $\pi_1(\mathbb{P}^2 \setminus B) \cong \mathbb{Z}/(2) * \mathbb{Z}/(3),$ $\pi_1(\mathbb{P}^2 \setminus B') \cong \mathbb{Z}/(2) \times \mathbb{Z}/(3).$

For a simple sextic B with

$$\Phi_B: X_B \to Y_B \to \mathbb{P}^2,$$

let \mathcal{E}_B be the set of exceptional curves of $X_B \to Y_B$, and let

$$\Sigma_B := \langle [E] \mid E \in \mathcal{E}_B \rangle \oplus \langle h_B \rangle \subset H^2(X_B, \mathbb{Z}),$$

where h_B is the class of the pull-back of a line. We have

$$B \sim_{\mathrm{cfg}} B' \Rightarrow \Sigma_B \cong \Sigma_{B'}$$
.

We denote the primitive closure of Σ_B by

$$\overline{\Sigma}_B \subset S_{X_B} \subset H^2(X_B,\mathbb{Z}).$$

After the partial results by Urabe, Yang (1996) made the complete list configuration type of simple sextics by classifying all such $\overline{\Sigma}_{R}$.

We write $B \sim_{\text{emb}} B'$ if there exists a homeomorphism

$$\psi: (\mathbb{P}^2, B) \cong (\mathbb{P}^2, B').$$

We have $B \sim_{\mathrm{emb}} B' \implies B \sim_{\mathrm{cfg}} B'$.

of config types = 11159 < # of emb-top types =?

Definition

A Zariski pair is a pair [B,B'] of projective plane curves of the same degree with only simple singularities such that $B \sim_{\text{cfg}} B'$ but $B \not\sim_{\text{emb}} B'$.

We consider the finite abelian group

$$G(B) := \overline{\Sigma}_B/\Sigma_B$$
.

We put

$$\Theta_B := (\Sigma_B \subset H^2(X_B, \mathbb{Z}))^{\perp}.$$

Theorem

If $B \sim_{\mathrm{emb}} B'$, then $\Theta_B \cong \Theta_{B'}$.

In fact, Θ_B is a topological invariant of the open surface

$$U_B:=\Phi_B^{-1}(\mathbb{P}^2\setminus B)\ \subset\ X_B,$$

because we have $\Theta_B \cong H^2(U_B,\mathbb{Z})/\operatorname{Ker}$, where

$$\operatorname{Ker} := \{ \ v \in H^2(U_B) \ | \ \langle v, x \rangle = 0 \text{ for all } x \in H^2(U_B) \ \}.$$

Since the discriminant groups of $\overline{\Sigma}_B$ and Θ_B are isomorphic, we have:

Corollary

If
$$B \sim_{\text{cfg}} B'$$
 but $|G(B)| \neq |G(B')|$, then $B \not\sim_{\text{emb}} B'$.

This corollary produces many examples of Zariski pairs.

Example¹

In Zariski's example [B, B'] with $R_B = R_{B'} = 6A_2$, degs B = degs B' = [6] and

$$\pi_1(\mathbb{P}^2 \setminus B) \cong \mathbb{Z}/(2) * \mathbb{Z}/(3), \quad \pi_1(\mathbb{P}^2 \setminus B') \cong \mathbb{Z}/(2) \times \mathbb{Z}/(3),$$

we have $G(B) \cong \mathbb{Z}/3\mathbb{Z}$ and G(B') = 0.

troduction Lattice theory Polarizations **Zariski pairs**

Singular K3 surfaces

Definition

A K3 surface X is called *singular* if rank(S_X) = 20.

Theorem (Shioda and Inose)

The map

$$X \mapsto T(X) := (S_X \subset H^2(X,\mathbb{Z}))^{\perp}$$

is a bijection from the set of isom. classes of singular K3 surfaces to the set of isom. classes of oriented positive-definite even lattices of rank 2.

Theorem (Shioda and Inose)

Every singular K3 surface X is defined over $\overline{\mathbb{Q}}$.

Theorem (S. and Schütt)

Let X and X' be singular K3 surfaces over $\overline{\mathbb{Q}}$ such that $q_{\mathcal{T}(X)} \cong q_{\mathcal{T}(X')}$. Then there $\exists \ \sigma \in \operatorname{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ such that $X' \cong X^{\sigma}$.

If B is a simple sextic with total Milnor number $\mu(B) = 19$, then X_B is a singular K3 surface with $\Theta_B \cong T(X_B)$.

Corollary

Let B be a sextic with $\mu(B)=19$ defined over $\overline{\mathbb{Q}}$. If \exists an even pos-def lattice T' of rank 2 with $q_{T'}\cong q_{T(X_B)}$ and $T'\not\cong T(X_B)$, then $\exists \ \sigma\in \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ such that $B\not\sim_{\mathrm{emb}} B^{\sigma}$.

The first example revisited

Consider the config type of sextics B = L + Q, where

- $\deg L = 1$, $\deg Q = 5$,
- L and Q are tangent at one point with multiplicity 5 (A_9 -singularity), and
- Q has one A_{10} -singular point.

Such sextics are projectively isomorphic to

$$z\cdot (G(x,y,z)\pm \sqrt{5}\cdot H(x,y,z))=0,$$

where G(x, y, z) and H(x, y, z) are homogenizations of the polynoms in the 1st slide with $L = \{z = 0\}$.

The genus corresponding to $(D_{\overline{\Sigma}_B}, -q_{\overline{\Sigma}_B})$ and signature (2,0) (that is, the genus containing $T(X_B)$) consists of

$$\begin{bmatrix} 2 & 1 \\ 1 & 28 \end{bmatrix} (for + \sqrt{5}), \qquad \begin{bmatrix} 8 & 3 \\ 3 & 8 \end{bmatrix} (for - \sqrt{5}).$$
